

The Datastorage System is designed to handle secure ingestion,retention and retrieval of individual patientData. The core of the System is the DataStorage class it manages the iteration and holds the Data Structure to Store everything. Additinally we added DataDeletionPolicy to a separate class so that the retention rules can be easily changed without modyfing DataStorage.

The PatientData class encapsulates each individual Patient Object Individually, which is mapped in the Patient Map in DataStorage.

To secure not everyone but only eligible People can Access specific data we have a AccesControlManager class. This one is called after the DataRetriever gets a request and then needs to verify if the Person Requesting is eleigible or not. This design ensures full encapsulation and a clean and easy visible architecture.
